September 30, 1986

The Honorable William Proxmire United States Senate

Dear Senator Proxmire:

In a February 5, 1985, letter, you asked us to conduct a nationwide, statistical survey to determine the Postal Service's error rate in computing postage on individual letters and parcels that must be weighed to determine correct postage. You were concerned about allegations that the Service overcharged postal customers in a particular metropolitan area for mailing letters and parcels.

We subsequently met with a representative of your office and discussed the extensive time and resources that would be required for a nationwide survey. Your representative agreed that we would conduct a statistical survey in two geographic areas—Washington, D.C., and one other—rather than conducting a nationwide survey. We selected the Cincinnati/Dayton, Ohio, area as the additional geographic area. We concentrated our work on internal controls and procedures used by the Service to insure that postal customers are charged only established rates to mail letters and parcels. For the two geographic areas, we sought to determine the nature and extent of postage errors, if any, and whether scale maintenance procedures affected the accuracy of postage paid by postal customers.

Based on statistical sampling of mail in the two geographic areas, we found that postage calculations were accurate most of the time. We sampled 3,001 pieces of mail in the Washington, D.C., area. We found that individual mailers were incorrectly charged for postage 3.4 percent of the time when they presented a letter or parcel to a window clerk for mailing. Of the 2,924 pieces of mail we sampled in the Cincinnati/ Dayton, Ohio, area, individual mailers were charged the incorrect postage 1.9 percent of the time. The incorrect postage—about evenly split between overcharges and undercharges—resulted from errors by window clerks who used incorrect rate information, misread scales, or used inaccurate scales. Additionally, we found that some postage to their mail before presenting it to a window clerk.

We tested both electronic and mechanical scales for accuracy and found that 25 of the 198 tested, or about 13 percent, were inaccurate by the Service's maintenance standards. However, inaccurate scales may not

3.

always cause errors in the postage charged. To affect the accuracy of postage calculations, the scale error as it relates to the weight of the mail must be sufficient to cause the selection of the wrong weight range allowed by the rate schedule.

To ensure greater accuracy in retail operations, the Service is replacing older scales with new electronic scales. Our tests showed that electronic scales were more accurate than mechanical scales. Also, the Service has purchased certified test weights for each retail office to test scales daily for accuracy. As of May 1986, about 90 percent of the retail offices had received the test weights. Scale accuracy should be improved as a result of these actions. The results of our work are discussed in detail in appendix I.

In commenting on our draft report, the Service agreed that some postage errors do occur and stated that it is striving to reduce their frequency. The Service mentioned several measures under way, some of which we note in our report, that it feels should further increase the accuracy of postage calculations. The Service's comments, including the specific actions being taken by the Service, are in appendix II.

As agreed with your office, unless you publicly announce its contents earlier, we plan no further distribution of this report until 30 days from its issuance date. At that time, we will send copies to the Postmaster General; the Director, Office of Management and Budget; and other interested parties.

Sincerely yours,

22,9. Unders

William J. Anderson Assistant Comptroller General

ž.

Introduction	The United States Postal Service provides many types of mailing ser- vices to the public, and virtually every person is affected by the postal system. Because of the complexity of postal rate information, individ- uals generally rely on the Service to charge them the correct amount of postage to mail letters and parcels. The postal rate schedules contain an immense variety of fees and mailing information for each mail classification.		
	The Service has categorized mail by class and developed postage rates for each mail classification. There are five domestic mail classifica- tions—First-, second-, third-, and fourth-class and Express Mail. Within each of these mail classifications, there are many subclasses. For example, under the first-class category, there are subclasses for post cards, letters, and parcels (priority mail). All letter mail receives the first-class rate when mailed by individual customers. However, a parcel may be mailed in several ways depending on its weight.		
	Any mailable parcel could qualify for first-class rates, with a few excep- tions. Parcels that are not sent as First-Class Mail and which weigh less than 16 ounces are sent at third-class rates, unless there is a lower fourth-class rate for which the mail could qualify. Fourth-class rates are available for parcels weighing at least 1 pound that are not mailed at first-class rates. In addition, for expedited service, several Express Mail service options are available. Consumers may also elect to use one of the special services available at an additional charge. Individuals do not use the second-class rates. These rates are designed for mailers of magazines, newspapers, and periodicals, including nonprofit and class- room publications. Foreign mail may be sent using international rates and fees.		
Objectives, Scope, and Methodology	Our objective was to obtain an indication of the nature, extent, and causes of any Postal Service errors in calculating postage costs for indi- vidual letters and parcels.		
	In discussions with the requester's office, we agreed to limit our work to two geographic areas, since a reasonable nationwide sampling error would be costly to obtain. Our work concentrated on internal controls and procedures used by the Service to ensure that postal patrons pay only established rates to mail letters and parcels. In performing this review, we sought to		

2019 C. C. C.

- determine the nature and extent of any postage errors in the two geographic areas and, where possible,
- determine whether errors were caused by window clerks or by inaccurate scales.

To determine the nature and extent of postage errors, we statistically sampled postage calculations in two areas-the Washington, D.C., area and the Cincinnati/Dayton, Ohio, area. Postal facilities in these areas, 21 in the Washington, D.C., area and 24 in the Cincinnati/Dayton area, were statistically selected based on fiscal year 1984 postal revenue. The probability of being selected was greater for facilities with the largest revenues. The Washington, D.C., sampling area was comprised of the areas served by the District of Columbia Post Office and the Northern Virginia and Prince Georges (Maryland) Management Sectional Centers (MSCs). The other sampled area included the areas served by the Cincinnati and Dayton, Ohio, MSCs. We weighed and computed the postage for 3,001 pieces of mail in the Washington, D.C., area, and 2,924 pieces of mail in the Cincinnati/Dayton area. We compared our computations with postage affixed to the mail pieces. The sampling of mail was limited to mail accepted by window clerks. The sampled mail did not include second-class mail, COD, registered and insured mail because these types of mail require special or additional acceptance procedures. The sample results, which are statistically weighted, are representative only of the geographic area included in each sample for similar mail accepted by window clerks. Both samples have a 95 percent confidence level with a plus or minus 5 percent sampling error. The selection of the two geographic areas was based solely on the availability of GAO staff to perform the review.

At all four MSCs and the District of Columbia Post Office, we interviewed plant maintenance staff to determine whether internal controls and procedures were in place to ensure that scales were accurate. We tested selected internal controls and procedures and determined whether scales at sites visited were approved for use. We reviewed applicable maintenance bulletins, manuals, and instructions. With the use of certified test weights, we performed limited independent testing of scales during our statistical sampling of letters and parcels. We also contacted officials at the National Bureau of Standards to obtain information on standards for postal scales.

Our review was performed from August 1985 to December 1985 in accordance with generally accepted government audit standards.

Appendix I Accuracy of Postage Calculations in Two **Geographic Areas** Of the 5.925 pieces of mail sampled, we determined that 275 pieces did Some Errors Were not have correct postage. Of this total, errors on 158 pieces of mail (57 Made in Postage percent) were caused by the Service's window clerks. The remaining 117 Calculations pieces of mail with errors (43 percent) were caused by postal customers who affixed too much postage to letters and parcels before presenting the mail to a window clerk. Of the 3,001 pieces in the Washington, D.C., area sample, 103 pieces or 3.4 percent had postage errors caused by window clerks. The overcharges by window clerks amounted to \$25.02 for 53 pieces of mail. Undercharges totalled \$20.93 for 50 pieces of mail. In the Cincinnati/Dayton area, we determined that of the 2,924 pieces of mail sampled, 55 pieces, or 1.9 percent, had postage errors caused by window clerks. Overcharges by clerks were \$5.35 for 23 pieces of mail; undercharges totalled \$6.34 for 32 pieces of mail. We analyzed differences in postage calculations (by us and by window clerks) to ascertain the causes of the errors. We were not able to isolate a reason for the difference in all of the postage calculations. However, where we could do so, our analyses showed that the differences were due to the fact that window clerks misread scales, made errors in using rate information, or used scales that were not in tolerance ranges prescribed by the Service's maintenance manuals. Table I.1 summarizes the nature and extent of errors attributable solely **Postal Service Errors** to postal window clerks.

Intra-Bulk Mail Center Discount Not Given	 Fourth-class parcel post mail is eligible for a 16-cent discount when mailed within the same Bulk Mail Center (BMC)¹ as its destination. We found 18 instances where clerks did not give the discount when parcels were eligible for it. For example, parcels mailed from ZIP Code Prefix 454 in the Dayton, Ohio, sampling area are eligible for the 16 cent intra-BMC discount for destinations in ZIP Code Prefix 456. A window clerk charged a customer \$1.41 to mail a fourth-class parcel that weighed 1 pound and 7.9 ounces from a post office with ZIP Code Prefix 454 to a destination in ZIP Code Prefix 456. The correct postage for this parcel was \$1.25, but the clerk did not subtract the 16 cent intra-BMC discount.
Mail Accepted With Insufficient Postage	Sometimes postal customers present mail to a window clerk for mailing with a stamp(s) or a postage meter strip already affixed on the mail. In some instances, the window clerk(s) accepted the mail without verifying the accuracy of the postage. Our examination of mail handled by clerks showed that 26 pieces of mail having insufficient postage were accepted by window clerks in the Cincinnati/Dayton area. The Service lost \$4.20 in revenue on these pieces of mail.
	• A customer in the Dayton, Ohio, area gave a window clerk a piece of mail marked first-class which had \$1.75 postage already affixed. The window clerk accepted the item for mailing. We weighed this piece of mail on an electronic scale and determined that it weighed 10.3 ounces. The official Postal Service rate chart shows that First-Class Mail weighing more than 10 and less than 11 ounces should cost \$1.92 for all destinations within the United States.
Scale Maintenance	Postal scales are precision instruments that must be properly main- tained to ensure accuracy throughout their entire range. Only scales that are accurate should be used by window clerks to weigh letters and par- cels. Several types of mechanical and electronic scales (rate classifiers) are being used by window clerks. Electronic scales automatically com- pute weight and postage when the mail class is selected. All mechanical scales show weight information; however, some mechanical scales may also compute postage. Postal regulations require that window clerks zero balance and test each scale using certified test weights at the start

	Appendix I Accuracy of Postage Calculations in Two Geographic Areas
	of each day. In addition to these daily checks by window clerks, each scale is required to be checked for accuracy at least annually.
Zero Balancing Scales	Zero balancing means making sure that the scale reads zero at the zero indicator on the scale when no mail is on the scale's weighing platform. The Service requires daily zero balancing because it prevents some errors but does not require that a record of daily zero balancing be main- tained. Therefore we could not determine whether all scales were zero balanced daily as required by postal regulations. Electronic scales show weights in a digital display and maintain a zero tracking when no mail is on its weighing platform.
Checking Scales for Accuracy With Certified Test Weights	Postal regulations require that scales used at retail windows in post offices be checked for accuracy using certified test weights. Scales are to be checked daily and calibrated at least annually using certified test weights. Starting in the fall of 1985, small sets of certified test weights (a 5-pound weight and a 1-ounce weight) were being sent to post offices and contract stations ² so that window clerks could check scales daily. As of May 1986, about 90 percent of all retail offices had received their set of certified weights. The maintenance office in each MSC has overall responsibility for the annual check, which should be done in accordance with criteria described in several maintenance bulletins on testing of scales used to rate single pieces of mail. If a scale is checked for accu- racy under these instructions and is found to be not in compliance, it should either be calibrated and repaired or be taken out of service.
	The small sets of test weights are useful tools for providing local mana- gers and window clerks with a means of insuring scale accuracy and thus correcting any deficiencies that can occur between the required annual testings. The use of these small sets of certified test weights is not intended to replace the annual calibration checks. Calibration checks are still necessary because certified test weights other than a 5-pound and 1-ounce weight may be required to perform calibration checks throughout the 70-pound range of most postal scales.
	As we were completing our mail samplings, the certified test weights were still being mailed to post offices and contract stations in the geo- graphic areas we sampled. As a result, we could not determine whether they were being used on a daily basis as required.
	² Postal units located in businesses and operated under a contract by non-Postal Service personnel.

8 1911

Scale Accuracy	 At each of the post offices and contract stations included in our mail samples, we verified the accuracy of all scales used by window clerks. In testing scales for accuracy, we used certified test weights. The results of our tests showed that 14 of the 45 offices had at least one scale that did not weigh according to the Service's standards. The Service's standards are based on standards for postal scales established by the National Bureau of Standards. In total, we tested 198 scales, both electronic and mechanical. Two of the 61 electronic scales did not meet prescribed tolerance ranges and could result in incorrect postage being charged. One scale registered 4 pounds 13.6 ounces when tested with a 5 pound test weight. Another scale registered 5 pounds 2.5 ounces while weighing a 5 pound test weight. Both scales have since been replaced with newer electronic scales which we have determined to meet prescribed tolerances. Mechanical scales were more frequently inaccurate. In total, we found 23 of the 137 mechanical scales that we tested were not balanced exactly according to standards. Sixteen scales weighed lighter than the test weights, thus favoring the customer in some instances, while five scales weighed heavier than the test weights tending to favor the Service. Two scales weighed erratically; at different times, they weighed both heavier and lighter than the test weights. In most cases, inaccurate scales were taken out of service after we tested them. 				
					Our review of the records of annual scale checks in the MSCs showed that they were incomplete. In some instances, the records indicated that testing was not done. However, when records indicated that testing had been done, we could not determine whether testing was done according to maintenance requirements. Also, maintenance managers had no assurance that all scales had been tested.
				Inaccurate Scales May Not Always Cause Postage Errors	When an inaccurate scale is used, it does not necessarily mean that the accuracy of postage calculations will be affected all of the time. To affect the accuracy of postage calculations, the scale error as it relates to the weight of the mail must be sufficient to cause the selection of the wrong weight range allowed by the rate schedule. For example, the weight range for fourth-class parcel post zone rated mail is 1 pound. A scale error which does not change the weight of a parcel beyond or below the allowable range would not affect the rate charged the customer.

n gegen an start a star

	Appendix I Accuracy of Postage Calculations in Two Geographic Areas
Scale Improvements Are Being Made	The Service has recognized the need for improving the efficiency and effectiveness of retail window operations and is taking steps to achieve this goal. The Service's window automation program should enhance the accuracy and efficiency of retail postal operations utilizing computer technology.
	The retail window automation program is a nationwide campaign by the Service to modernize retail services by installing electronic equipment. Under this program, the Service intends to install new electronic rate classifiers to replace the older scales now being used in retail windows. This transition has already begun and is expected to take several more years. All post offices should have electronic scales when the program is completed in 1990. The conversion to electronic rate classifiers should result in greater accuracy, increased productivity, and improved cus- tomer satisfaction. Currently, two types of advanced electronic rate classifiers are being used in selected post offices. Both are microcom- puter terminals that combine the functions of an electronic scale, a pro- grammable calculator, and an information screen that allows customers to monitor their transactions. The systems also allow speedy record- keeping for the Service.
Conclusions	Based on statistical sampling of mail in two geographic areas, we found that postage calculations were accurate most of the time. We determined that postage errors attributable to the Service occurred 1.9 percent of the time in the Cincinnati/Dayton area and 3.4 percent of the time in the Washington, D.C., area. These errors occurred because postage was based on incorrect weight and rate information. Additionally, we found that some postage errors were caused by postal customers who affixed too much postage to their mail before presenting it to a window clerk. The Service has taken steps to improve the accuracy of postage calcula- tions. The installation of electronic rate classifiers should result in
	increased accuracy in rating individual pieces of mail as well as increased efficiency in serving postal customers. Now that certified test weights are available at most retail postal windows, including contract stations, scale accuracy should improve.

Comments From the United States Postal Service

ATES POSZA GUSMALL G
THE POSTMASTER GENERAL Washington, DC 20260-0010
July 31, 1986
Dear Mr. Anderson:
This refers to your draft report entitled <u>Postage Charges in Two</u> Geographic Areas Were Accurate Most of the <u>Time</u> .
The report finds that postage calculations at the offices you visited were accurate most of the time, but in a small percentage of transactions there were errors, about evenly split between overcharges and undercharges. These errors were caused by window clerks who used incorrect rate information, misread scales, or used inaccurate scales.
We know such errors do occur and we are striving to reduce their frequency. As the report notes, we are replacing older mechani- cal scales with more accurate electronic ones and are distribut- ing diagnostic test weights for the daily testing of all scales. We are also issuing new instructions to post offices emphasizing the need for accurate mail classification and rating and for the daily balancing of scales. We believe these measures will further increase the accuracy of our postage calculations.
Thank you for the opportunity to comment on your report.
Sincerely,
Mr. William J. Anderson Director General Government Division United States General Accounting Office
Washington, D.C. 20548-0001
